

Start here

Field Kit helps you plan a setup, check a connection and keep useful notes. Pick the job you have in front of you.

1 Choose what you want to do

The four buttons on Home are the easiest way in. For a first look, tap Check a connection.

2 Name your setup

Save your drone or test rig under Equipment. You can reuse its radio and battery settings instead of typing them again.

3 Looking for something specific?

Tap Tools or Search. Try a word such as GPS, cable or battery to find the right tool.

You don't need to learn all 20 tools

Start with one task. Come back to Home when you want to try something else.

What the app does

Field Kit calculates, checks incoming data and saves notes. It does not fly the drone, flash firmware or change a device's settings.

Give your setup a name

Open Equipment. A name makes it much easier to tell one drone's settings and reports from another's.

The screenshot shows the 'Equipment' screen in the Prismo Field Kit app. At the top, there's a back arrow, the title 'Equipment', a star icon, and a search bar. Below this, a note says 'Equipment optional · calculators use the entered inputs' and there's an 'Equipment' button. The main section is titled 'My equipment' with a subtitle 'Save your equipment once and reuse its calculator inputs.' and a link 'How to use this'. Under 'Saved equipment', there's a dropdown menu 'Choose a profile'. The 'Name your equipment' section has a subtitle 'Give it a name. Add a serial to save per-drone checks.' and two input fields: 'Equipment name' (containing 'Demo quad') and 'Asset serial (optional)' (containing 'DEMO-001'). A note below these fields says 'Uses your current calculator inputs. Review the settings below before estimating.' At the bottom of this section is a large green 'Save equipment' button. Below that is a link 'Radio & antenna inputs'. The bottom navigation bar has four icons: Home, Equipment (highlighted), Saved checks, and Tools. Three numbered callouts are present: 1 points to the 'Equipment name' field, 2 points to the 'Asset serial (optional)' field, and 3 points to the 'Save equipment' button.

1 Use a name you will recognize

“Demo quad” is used in this guide. Use the name you normally call your own drone or test rig.

2 Add the serial number if you have it

You can leave this blank for calculators. You will need a serial number to save a connection check against a particular drone.

3 Save, then check the settings

Tap Save equipment. Open the radio, battery and hardware sections below and check their values before using the calculators.

Use it again next time

Your saved setup appears on Home and above the tools. Open Equipment whenever you need to edit it.

Example equipment: Demo quad, serial DEMO-001.

One useful distinction

These are settings for the app's calculations. Saving them does not program your radio or flight controller. Terrain and mesh have their own radio selections.

Try it without a drone

Home > Check a connection > Practice. You can learn this part of the app without plugging anything in.

1 Tap Practice

This runs a software example. You can switch to USB cable or Wi-Fi / Ethernet later, when you want to check real equipment.

2 Pick an example

Start with Healthy telemetry. Then try a fault such as No data, bad frames or stale telemetry to see how the result changes.

3 Tap Try this example

Read the message that appears. Open the details below if you want to see what led to it.

A good first five minutes

Run one healthy example and one fault. That is enough to get a feel for the connection checker before you use a cable.

About the examples

Practice results are labeled SOFTWARE SIMULATION. They show how the app responds; they are not readings from your drone.

Read the message, then the details

The connection checker puts the next thing to try near the top, so you do not have to decipher every row first.

1 Check where the result came from

This example is simulated. When you check equipment, this area identifies the connection being used.

2 Try the suggested next step

Here, No data is arriving points you toward the cable, port or sender. In Practice, Try another fault lets you explore a different example.

3 Open a row if you need more detail

Transport, Protocol, Telemetry and Video answer different questions. Tap a row to find out what the app saw.

What to tell someone else

Describe the message and the connection you checked. That is more useful than saying the whole drone “doesn't work.”

Keep the links separate

A drone may still have control and video even when no GPS telemetry reaches this app. Check each connection on its own.

Save what happened

After a check, scroll down and open Save a per-drone test record. Use equipment with a serial number.

1 Say who ran the check

Enter the operator or station. Add a work order if you use one.

2 Write the useful details

What did you connect? What worked? What still needs checking? Include video behavior if you checked it separately.

3 Tap Save diagnostic snapshot

The app saves the check, its equipment settings and your notes. Open Saved checks to find it later.

Make the next check easier

A short, specific note can save you from repeating the same troubleshooting next week. If you changed calculator settings during the session, start a fresh check before saving.

Save a copy you can keep

The app keeps the latest 50 snapshots on this device. Export anything you need long term. Saving a check does not automatically mark the drone as passed.

Send someone the report

Open Saved checks, find the right entry, then tap Export readable report.

1 Choose the right drone

Check the name and serial number before exporting.

2 Check the date and type of check

An old report keeps the settings used at that time. Practice reports keep their simulation label.

3 Save the file, then share it

Android asks where to save the HTML report. Once saved, send that file using your usual sharing app.

They can read it without Field Kit

The report opens in a browser. It includes the results and notes, with more detail available farther down.

Reading this guide

The screenshots use an example drone and practice data. Android's permission prompts and file picker are not shown.
